VARIATIONS IN CLIMATIC CHARACTERISTICS AS  
RELATED TO EVAPOTRANSPIRATION IN SOUTH PARK  
CENTRAL PARK COUNTY, COLORADO

By Norman E. Spahr

ABSTRACT

Data collected during May through September in 1977, 1978, and 1979 at the towns of Jefferson and Fairplay, and at Antero Reservoir were analyzed to determine variations in climatic characteristics in South Park. An analysis of variance technique was used to determine between-station differences in climatic characteristics. Knowledge of these climatic characteristics will aid State and local agencies in determining the amount of water that may be transferred from agricultural use in South Park to municipal use in the Denver metropolitan area.

Results of the analysis of variance of the climatic characteristics can be summarized as follows:

1. Daily maximum temperature was statistically different between the Fairplay and Antero Reservoir stations and between the Jefferson and Antero Reservoir stations at the 1-percent level of significance. Daily maximum air temperature was greater at the Antero Reservoir station than at the Jefferson and Fairplay stations.
2. Daily minimum air temperature was statistically different between the three stations at the 1-percent level of significance. The Antero Reservoir station had the greatest average and the Jefferson station the lowest average daily minimum air temperature.
3. Daily average air temperature from the hygrothermograph records was statistically different between all stations at the 1-percent level of significance. The Antero Reservoir station had the highest and the Fairplay station the lowest daily average air temperature.
4. Daily pan evaporation was statistically different between the Jefferson and Fairplay stations and between the Jefferson and Antero Reservoir stations at the 1-percent level of significance. The Fairplay and Antero Reservoir stations had greater daily pan evaporation than the Jefferson station.
5. Daily cumulative wind was statistically different between the three stations at the 1-percent level of significance. The cumulative wind was greatest at the Fairplay station and lowest at the Jefferson station.

6. Daily relative humidity was statistically different between the three stations at the 1-percent level of significance. The Jefferson station had the highest and the Fairplay station the lowest relative humidity.

7. Daily solar radiation was statistically different between the three stations at the 1-percent level of significance. Solar radiation was greatest at the Jefferson station and least at the Antero Reservoir station.

8. Daily precipitation was not significantly different between the three stations.

Estimates of potential evapotranspiration made using the Penman equation were not significantly different between the three stations. The lack of spatial variations in the estimated potential evapotranspiration indicates that no one climatic characteristic can be used as an indicator of spatial variation of potential evapotranspiration. Variations in solar radiation, as much as 101 langleys per day, between the stations at Jefferson, Fairplay, and Antero Reservoir indicate that solar radiation needs to be measured at sites where evapotranspiration is being determined.

With the exception of precipitation during 1977 at the Antero Reservoir station, seasonal precipitation during 1977-78 at all the study stations was less than the 17-year mean seasonal precipitation at Antero Reservoir. In 1979, all stations had greater seasonal precipitation than the 17-year mean seasonal precipitation at Antero Reservoir. During 1977, the seasonal average air temperature at Antero Reservoir was greater than the 17-year mean, during 1978 it was about equal to the 17-year mean, and during 1979 it was slightly below the 17-year mean.

## INTRODUCTION

To provide State and local agencies with data that could be used in determining the amount of water that may be transferred from agricultural use in South Park to municipal use in the Denver metropolitan area, the U.S. Geological Survey, in cooperation with the City and County of Denver, Board of Water Commissioners, conducted a 3-year investigation of climatic characteristics in South Park. Colorado courts have held that the entity purchasing a transfer in water use and point of diversion may obtain only the amount consumptively used by the original right. Therefore, information about the consumptive use is necessary for the reallocation of water resources. Evapotranspiration is one part of the total consumptive use.

The objectives of the study were to determine if spatial variations of climatic characteristics exist and, if so, to determine the magnitude of the variations. Relationships between climatic characteristics and potential evapotranspiration also were investigated to determine if the principal factors controlling the spatial variations of potential evapotranspiration could be identified.

Appreciation is extended to the station observers, David Paprocki, William Strayer, Denise Moore, Peter Bensen, and Daniel Nyman, for their assistance in collecting the climatic data. Appreciation also is extended to Thomas Kelsay of the National Weather Service for inspecting the station sites and installations to insure that representative data could be collected, and to Brent Troutman of the U.S. Geological Survey for aid in applying analysis of variance to climatic data.

### DESCRIPTION OF SOUTH PARK

South Park is an intermontane valley located in west-central Park County (fig. 1). The park is bounded on the west and north by the Park Range, on the east by the Tarryall Mountains and Puma Hills, and on the south by Black and Thirtynine Mile Mountains. Tributaries of Tarryall Creek drain the northern part of the park and the South Platte River and tributaries drain the remainder of the park. South Park has an area of about 400 square miles. Altitudes within the park range from about 8,800 to about 9,900 feet.

Community and domestic water supply and irrigation of native grasses for use as livestock feed are the principal uses of water in the park. Hay production generally is limited to a single cutting each year because of the short growing season.

### DATA COLLECTION AND CONVERSION

Climatic data suitable for use in this study were available from the National Weather Service only for the precipitation gage at Hartsel operated from 1909 to 1964 and for the precipitation and temperature station at Antero Reservoir operated since 1961. To collect additional data for this study, three stations were established at Jefferson, Fairplay, and Garo, and additional instruments were added to the station at Antero Reservoir. Instruments were installed at the stations during the spring of 1977. Station locations are shown on figure 1 and physical characteristics of the stations are listed in table 1.

Table 1.--Descriptions of stations at which climatic data were collected

Station	Location <sup>1</sup>		Altitude (feet)	Description of location	Ground cover at station	Ground cover of surrounding area
	Latitude North	Longitude West				
Jefferson-----	39°22'32"	105°48'12"	9,500	West edge of town	Grass	Irrigated ranch-land.
Fairplay-----	39°13'27"	105°58'57"	9,870	0.2 miles south of town	Native range-land	Native rangeland.
Garo-----	39°05'10"	105°52'02"	9,110	2.0 miles south of town	----do----	Irrigated ranch-land; low ridge to east.
Antero Reservoir.	38°55'36"	105°52'37"	8,910	0.2 miles south- east of reservoir	----do----	Native rangeland; reservoir to northwest.

<sup>1</sup>Location shown on figure 1.

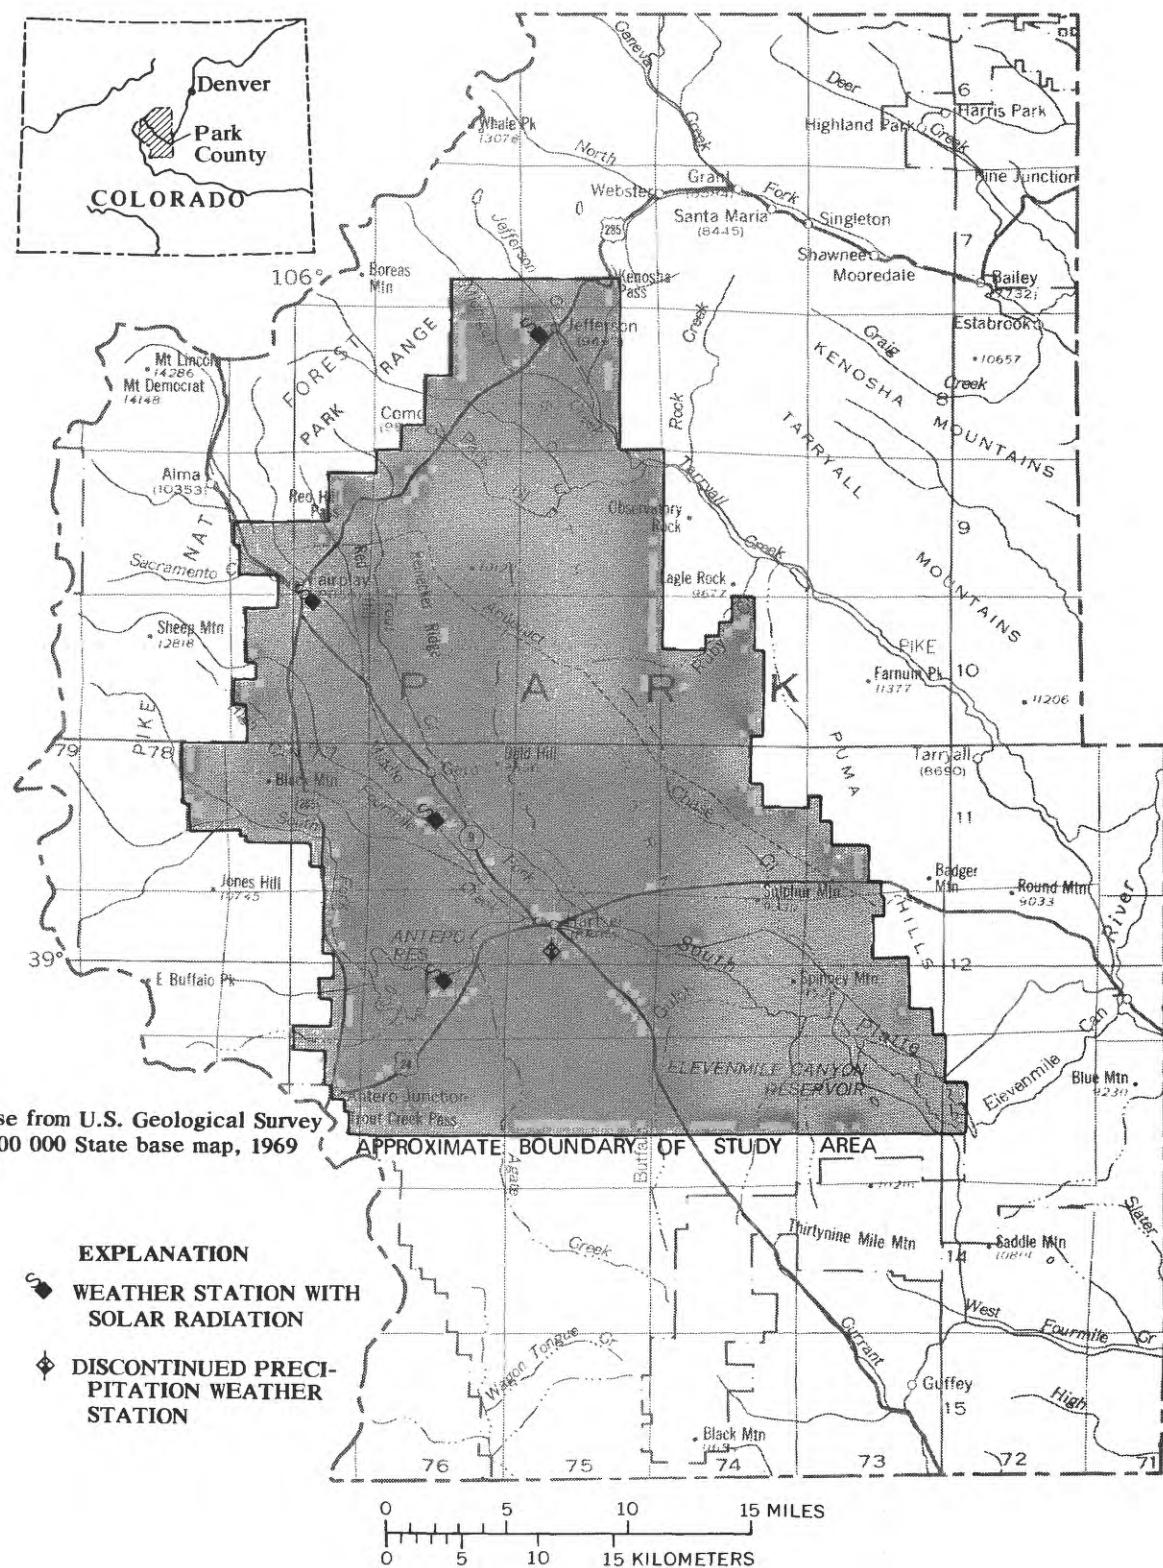

Figure 1.--Location of study area and weather stations.

The study originally was to collect data during the 1977 and 1978 growing seasons (May through September) but a third season (1979) of data was collected for some characteristics. Observations were made in the morning at the Jefferson, Garo, and Antero Reservoir stations and in the afternoon at the Fairplay station. All data were collected according to standard procedures of the National Weather Service (1972).

The types of climatic data collected at each station are listed in table 2. Hygrothermograph data were not collected in 1979. Continuous records from the hygrothermographs and radiometers were converted to average daily values by electronically digitizing the areas of the graphical output. With the exception of the daily precipitation data, daily values were combined to determine 7-day (for example, May 1 through May 7) means of each type of data. The combining of daily values to weekly means was done to simplify the data analysis. Daily precipitation values were converted to 7-day total-precipitation values for analysis. Because only a limited amount of data were collected at the Garo station, these data were not used in the statistical analyses. Tabulations of the data collected at the stations are found in the Supplemental Information section (Jefferson station, table 4; Fairplay station, table 5; Antero Reservoir station, table 6; and Garo station, table 7).

#### STATISTICAL ANALYSIS OF CLIMATIC DATA

Time graphs for the 7-day means of daily maximum temperature at Jefferson, Fairplay, and Antero Reservoir stations are shown in figure 2 for May-September 1977, 1978, and 1979; and 7-day means of daily minimum temperature at Jefferson, Fairplay, and Antero Reservoir stations are shown in figure 3 for May-September 1977, 1978, and 1979. Time graphs for the other climatic characteristics analyzed (figs. 6-12) are found in the Supplemental Information section. Points are plotted at the median of the 7-day period.

The magnitude of the differences between stations and the week-to-week variations at a single station is apparent in both figures 2 and 3. To eliminate any effect of the week-to-week variations on the differences between stations, a three-way analysis of variance was used to analyze station differences.

The equation used for the analysis of variance was modified from Graybill (1976) and has the form:

$$x = \mu + \alpha_i + \beta_j + \gamma_{k(j)} + \epsilon_{ijk} \quad (1)$$

where:

$x$ =measured value of variable;

$\mu$ =overall mean;

$\alpha$ =fixed effect due to station location;

$\beta$ =fixed effect due to week of the year;

$\gamma$ =random effect due to year measurements were made; and

$\epsilon$ =random error term.

Subscripts in equation 1 are standard matrix notations for nested analysis of variance (Graybill, 1976).

Table 2.--Types of climatic data collected at stations

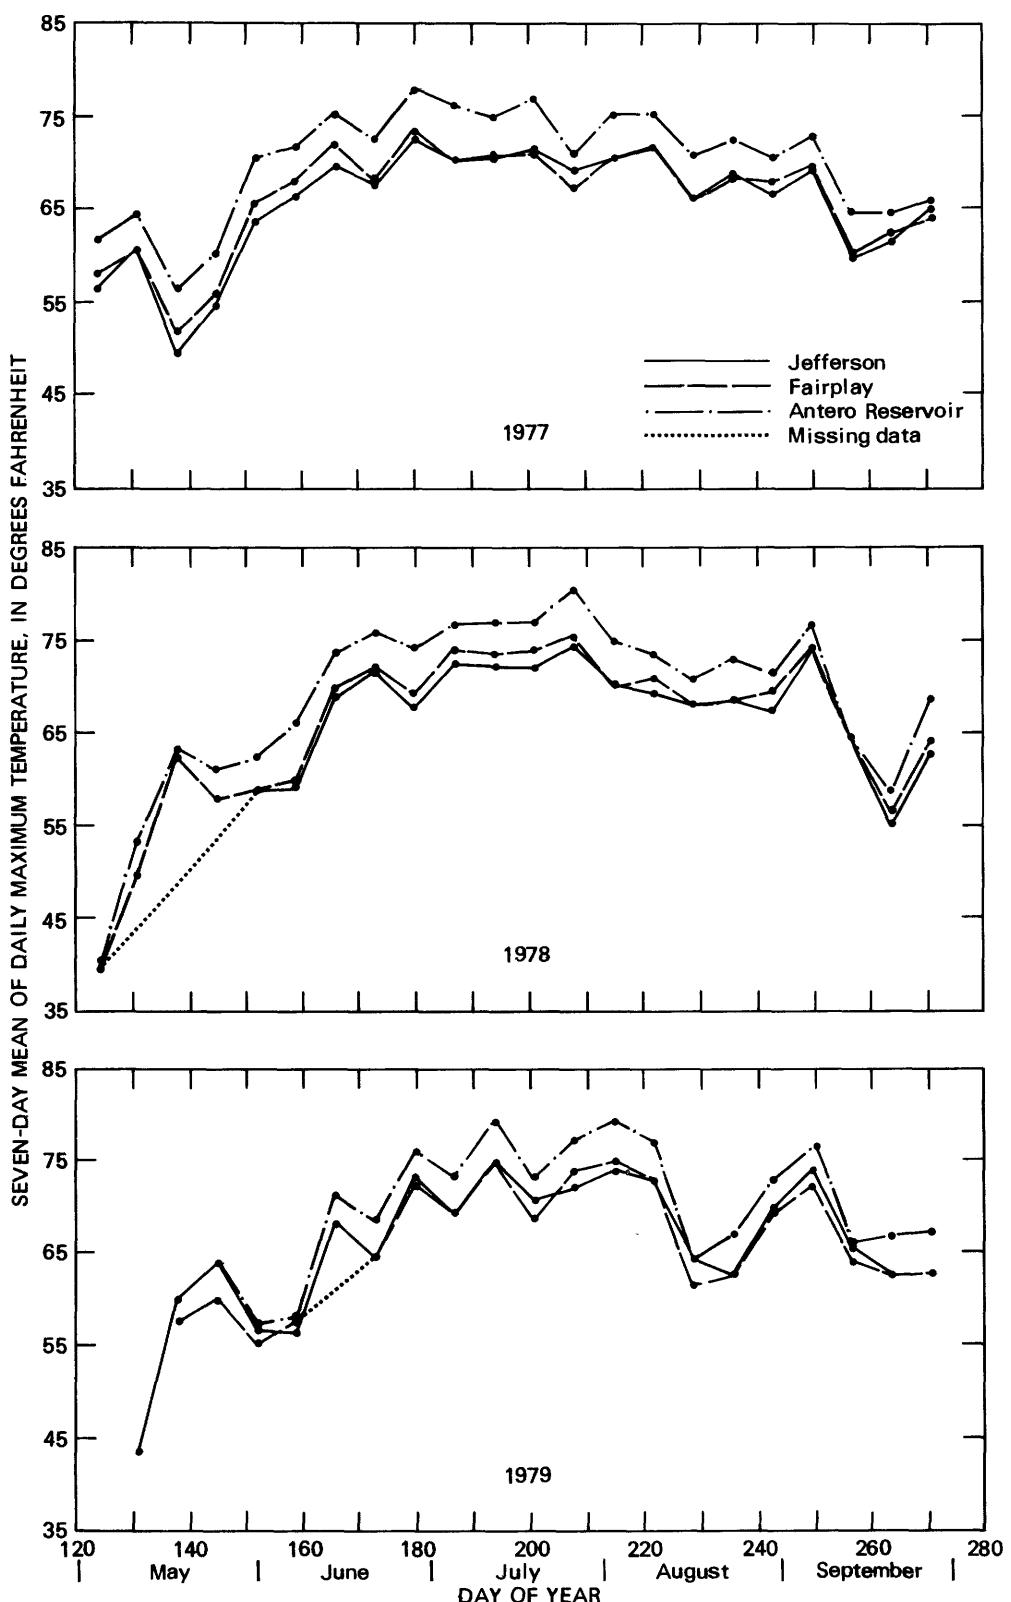

Type of climatic data	Instrumentation <sup>1</sup>	Approximate error
Daily maximum air temperature---	Maximum thermometer-----	±1 degree Fahrenheit.
Daily minimum air temperature---	Minimum thermometer-----	±1 degree Fahrenheit.
Daily pan evaporation-----	Hook gage-----	±0.01 inch.
Daily precipitation-----	Eight-inch rain gage-----	±1-5 percent.
Daily cumulative wind-----	Three-cup totalizing anemometer--	±1.5 miles per day.
Average daily air temperature <sup>2</sup> ----	Hygrothermograph-----	±1-2 degrees Fahrenheit.
Average daily relative humidity <sup>2</sup> ----	Hygrothermograph-----	±3-10 percent.
Average daily solar radiation----	Belfort radiometer <sup>3</sup> -----	±5-10 percent <sup>4</sup> .
Observation dry-bulb temperature----	Sling psychrometer-----	±1 degree Fahrenheit.
Observation wet-bulb temperature----	Sling psychrometer-----	±1 degree Fahrenheit.
Daily maximum pan-water temperature--	Submerged sixes thermometer-----	±1 degree Fahrenheit.
Daily minimum pan-water temperature--	Submerged sixes thermometer-----	±1 degree Fahrenheit.

<sup>1</sup>The use of names in this report is for identification purposes only and does not imply endorsement by the U.S. Geological Survey.

<sup>2</sup>Data for these characteristics not collected during 1979.

<sup>3</sup>An Eppley pyranometer was used to measure solar radiation at Antero Reservoir for 1977 and 1978; a Belfort radiometer was used in 1979.

<sup>4</sup>From Reifsnyder and Lull (1965).

**Figure 2.-- Seven-day mean of daily maximum temperature, Jefferson, Fairplay, and Antero Reservoir stations, May-September 1977, 1978, and 1979.**

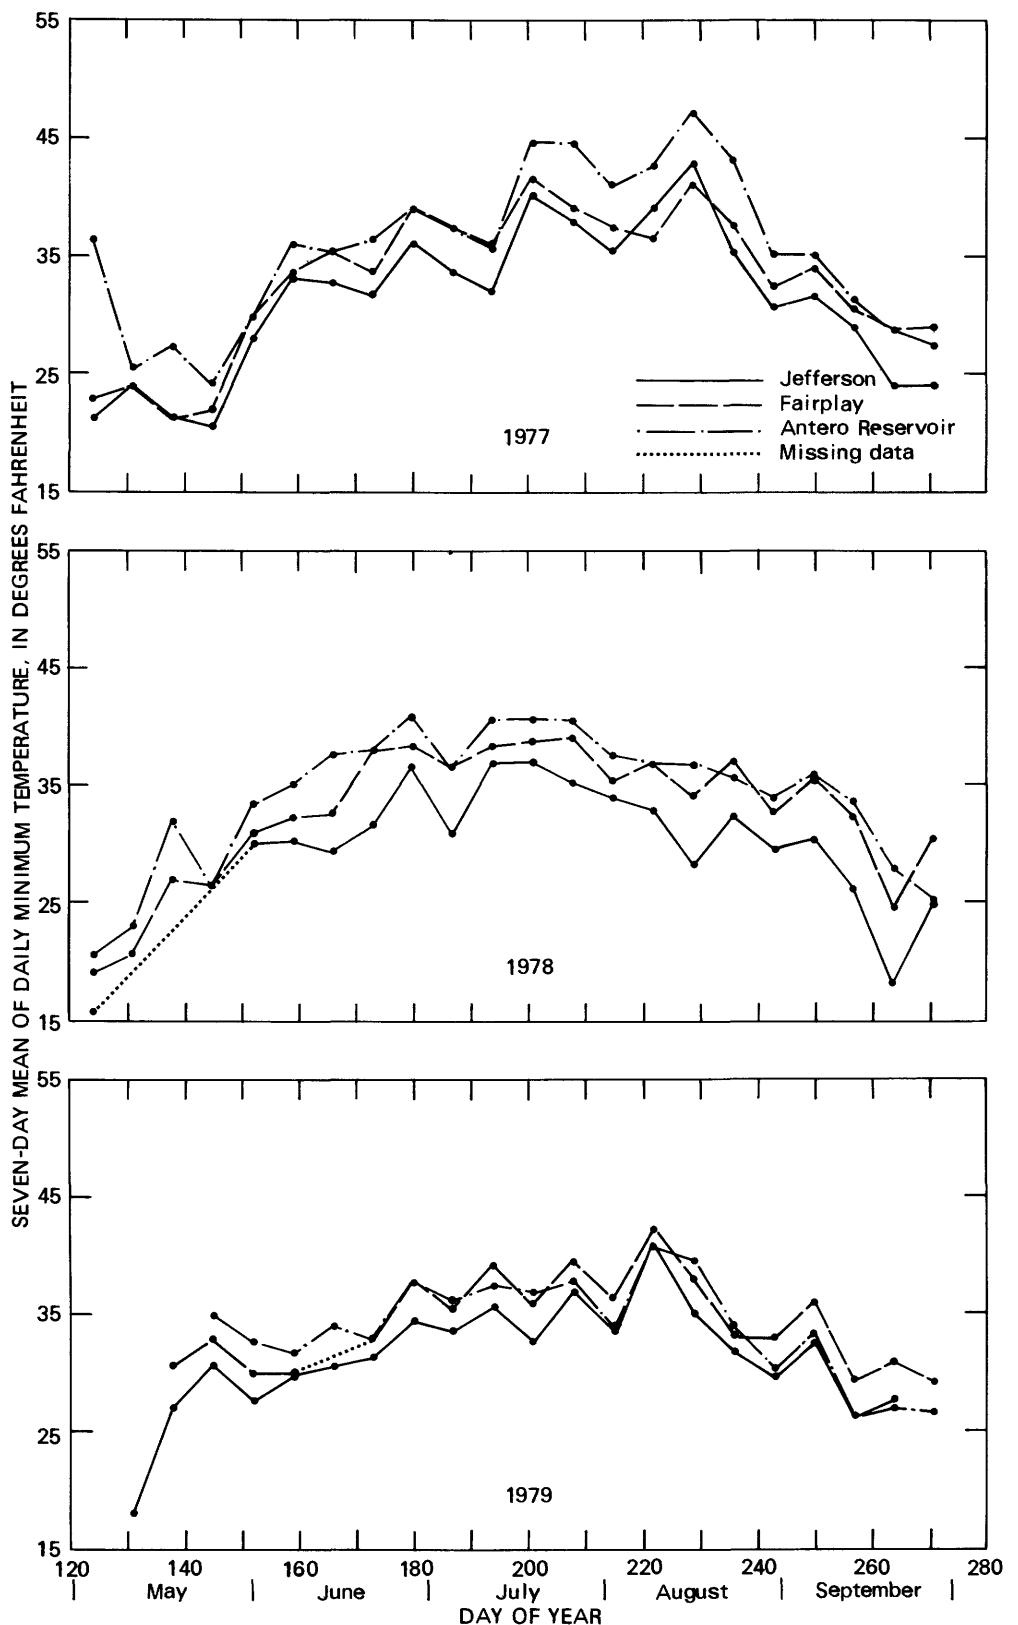

Figure 3.-- Seven-day mean of daily minimum temperature, Jefferson, Fairplay, and Antero Reservoir stations, May-September 1977, 1978, and 1979.

Equation 1 is known as a mixed three-way analysis of the sources of variation (station location, week of year, year, and error) with nesting of the source year within the source week of year. Equation 1 indicates that any given measured value ( $\chi$ ) is a function of the overall mean ( $\mu$ ) plus the fixed effect due to station location ( $\alpha$ ) plus the fixed effect due to the week of the year ( $\beta$ ) plus the random effect due to the year the measurements were made ( $\gamma$ ) plus a random error term ( $\epsilon$ ). By partitioning the total variation, that variation due solely to station location can be analyzed separately. Upon completion of the analysis of variance, an F test (Snedecor and Cochran, 1973) was used to determine if variations between all stations as a group were significant. A least-significant-difference (LSD) test (Snedecor and Cochran, 1973) was then used to analyze the differences between mean values for the climatic characteristics at the different station locations.

The values of the F test are not presented in the report because the analysis between pairs of stations is of more interest. However, in no instance was significance shown for the LSD test when the F test for that characteristic was found not to be significant.

The results of the analyses of variance and the LSD tests are shown in table 3; the first section presents the overall means and the number of weeks analyzed for each climatic characteristic by station, and the second section presents the differences between stations and the corresponding LSD values for each pair of stations. If the difference in overall means is greater than the adjacent LSD value, it can be assumed that the difference in overall means is significant at the 1-percent level of the LSD test.

The LSD values and the differences in means are estimates of population statistics of the various climatic characteristics and, as such, are based upon numerous point observations. Therefore, it is entirely possible that a particular LSD value may be less than the given instrumentation error because the error is describing a point observation and the LSD value is describing many observations.

## AREAL VARIATIONS IN CLIMATIC CHARACTERISTICS

Using table 3 as a guide, the differences in climatic characteristics between stations can be described. In the following sections, the term "significant" refers to the 1-percent level of significance by the LSD test.

### Temperature

Daily maximum air temperatures were significantly different between the Fairplay and Antero Reservoir stations and between the Jefferson and Antero Reservoir stations but were not significantly different between the Jefferson and Fairplay stations. Both daily minimum air temperatures and average daily air temperatures were significantly different between all three stations. Based upon the hygrothermograph data, daily average air temperatures are related to altitude, with the coldest temperature occurring at Fairplay (altitude, 9,870 feet) and the warmest temperature occurring at Antero Reservoir (altitude, 8,910 feet).

Table 3.—Results of analysis of variance and corresponding values of least-significant difference (LSD)

Values of least-significant difference at 1-percent level of significance.

Temperatures are in degrees Fahrenheit, evaporation and precipitation are in inches, relative humidity is in percent, and solar radiation is in langleys.

Climatic characteristic	Overall means and number of weeks analyzed (n)			Differences between stations and corresponding values of least-significant difference (LSD)							
	Jefferson		Fairplay	Antero Reservoir		Fairplay-Antero Reservoir		Jefferson-Fairplay Reservoir			
	Mean	n	Mean	n	Difference	LSD	Difference	LSD	Difference		
Daily maximum air temperature---	65.9	61	66.0	63	.01	0.5	3.8	0.5	3.9		
Daily minimum air temperature---	30.8	61	33.2	63	34.6	63	2.4	.8	1.4	.8	.8
Daily pan evaporation-----	.22	54	.28	58	.28	60	.06	.01	.00	.01	.06
Total weekly precipitation-----	.32	61	.29	64	.27	63	.03	.13	.02	.13	.05
Daily cumulative wind-----	66.3	61	84.0	61	76.2	61	17.7	4.4	7.9	4.4	9.9
Average daily air temperature----	51.8	29	50.7	32	55.1	32	1.1	1.0	4.4	1.0	3.3
Average daily relative humidity--	64.5	29	53.8	32	57.6	32	10.7	2.9	3.8	2.8	6.9
Average daily solar radiation---	560	61	491	63	459	54	69	19	32	19	101
										19	

Using the average of daily maximum and daily minimum temperature, the Jefferson station has a lower temperature than the Fairplay station. This apparent contradiction occurs because the hygrothermograph data is an integrated value whereas the average of maximum and minimum temperature is based upon two point values. The closeness of the maximum temperatures between Fairplay and Jefferson also should be noted. More data need to be collected to better define the temperature regime between these two stations.

#### Pan Evaporation

Daily pan evaporation was significantly different between the Jefferson and Fairplay stations and between the Jefferson and Antero Reservoir stations but was not significantly different between the Fairplay and Antero Reservoir stations.

#### Precipitation

Total weekly precipitation did not differ significantly between stations. The lack of significant differences does not necessarily mean that every storm distributed precipitation uniformly throughout the park. However, the lack of significant differences does indicate that, on the average, the total weekly precipitation resulting from all storms was about the same at all the stations.

#### Wind

Daily cumulative wind was significantly different between all stations. The degree of significant difference was the greatest of all the climatic characteristics. This indicates that daily cumulative wind may be a significant individual climatic characteristic affecting the total climatic conditions at all three stations and likely throughout the South Park area.

#### Relative Humidity

Average daily relative humidity was significantly different between all stations. However, because of the character of the hygrothermograph instrumentation, the 3.8-percent difference between the overall means of the Fairplay and Antero Reservoir stations may be within instrument accuracy. It should be noted that only two seasons of relative humidity data (1977 and 1978) were collected.

#### Solar Radiation

Average daily solar radiation was significantly different between all stations. The difference of 101 langleys per day between the overall means of the Jefferson and Antero Reservoir stations appears to be unusually large, and may be due to the variability in cloud cover as convective storms form and move over the park. The difference in instrumentation also may have an affect on this variability. All

radiometers were checked with an independent instrument but the Eppley<sup>1</sup> pyranometer used at the Antero Reservoir station is much more responsive than the mechanical radiometers used at the other stations. In 1979 mechanical radiometers were used at all three stations. The same type of variation was present; therefore, the instrumentation difference in 1977 and 1978 may not play a major role.

### ESTIMATES OF POTENTIAL EVAPOTRANSPIRATION

To show how the climatic characteristics are incorporated into an index value of evapotranspiration and to show the areal variation of the index, potential evapotranspiration values were determined for the Jefferson, Fairplay, and Antero Reservoir stations for 1977 and 1978. Because hygrothermograph data were not collected in 1979, estimates of potential evapotranspiration are not given for the 1979 season.

Potential evapotranspiration can be estimated using an equation derived by Penman (1948). This equation is a combination of the energy budget and the vapor-transport theories of evaporation, and represents potential water use from a well-watered, actively growing, short grass crop.

One form of the equation (American Society of Civil Engineers, 1973) is:

$$\epsilon = \frac{\Delta}{\Delta + \gamma} (R_n + G) + \frac{\gamma}{\Delta + \gamma} 15.36 (1.0 + .01U_2) (e_0 - e), \quad (2)$$

where:

$\epsilon$ =daily potential evapotranspiration, in langleys per day;

$\Delta$ =slope of saturation vapor pressure curve, in millibars per degrees Celsius;

$\gamma$ =psychrometric constant, in millibars per degrees Celsius;

$R_n$ =net radiation, in langleys per day;

$G$ =heat flux density from ground, in langleys per day;

$U_2$ =horizontal wind speed at 2 meters, in miles per day;

$e_0$ =saturation vapor pressure at average air temperature, in millibars; and

$e$ =vapor pressure at average dew-point temperature, in millibars.

The slope of the vapor pressure curve ( $\Delta$ ), the psychrometric constant ( $\gamma$ ), and the saturation vapor pressure ( $e_0$ ) were calculated using equations by Bosen and Brunt, as presented in American Society of Civil Engineers (1973, p. 123). The values of  $\gamma$  are based upon air pressure or defined by the standard pressure-altitude curve. The values of  $e_0$  and  $e$  were based upon hygrothermograph data.

---

<sup>1</sup>The use of the brand name in this report is for identification purposes only and does not imply endorsement by the U.S. Geological Survey.

In applying this equation to the South Park data, the ground-heat flux term was assumed negligible. The ground-heat flux is a minor contributor to the equation when compared to other heat terms; therefore, neglecting it does not seriously affect results.

Because of the lack of longwave-radiation data, net radiation was estimated from incoming solar radiation by use of a regression equation presented by the American Society of Civil Engineers (1973). The equation is  $R_n = 0.61R_s - 24$ , where  $R_s$  is solar radiation in langleys per day. Percentage errors for the equation were not given, but errors in the final potential evapotranspiration values will result from the net radiation estimates. The Penman (1948) formula yields daily estimates which were combined to find weekly mean values of potential evapotranspiration for the Jefferson, Fairplay, and Antero Reservoir stations. The analysis of variance technique was then used to investigate between-station variances.

The overall mean value of daily potential evapotranspiration was found to be 0.16 inch at Jefferson, 0.17 inch at Fairplay, and 0.17 inch at Antero Reservoir. Using the LSD test, a difference of greater than 0.01 inch between stations is necessary for the overall means to be statistically significant at the 1-percent level. Because the maximum difference between any two stations was only 0.01 inch, the estimated potential evapotranspiration was not significantly different between the Jefferson, Fairplay, and Antero Reservoir stations. These estimates of daily potential evapotranspiration are 0.03 inch less than values reported by Kruse and Haise (1974) for a site near Garo for the 1967-69 growing seasons. This small difference may be attributed to normal variation of climatic factors, differences in instrumentation, or differences in applying the Penman equation to measured climatic data.

The Penman equation estimates potential evapotranspiration. This can be thought of as an index. Actual evapotranspiration may be significantly different from the potential values. The derivation of actual evapotranspiration from potential evapotranspiration involves locally calibrating the potential estimates to measured evapotranspiration for the crop in question. The values given and conclusions drawn from these values should not be construed to apply to actual evapotranspiration in the South Park area.

The Penman equation is not the only equation available to determine potential evapotranspiration. It was chosen because most of the climatic characteristics known to affect evapotranspiration are included in the equation.

## RELATIONSHIP OF STUDY DATA TO HISTORIC DATA

Although the data collected during this study indicate that there is no significant difference in daily pan evaporation between the Fairplay and Antero Reservoir stations, data collected in previous studies indicate that there may be a significant difference in daily pan evaporation between Fairplay, Garo, and Antero Reservoir. According to Ficke and others (1977), pan evaporation at the Antero Reservoir station averaged 0.24 inch per day during May through September 1967-70, while pan evaporation at a site near Garo averaged 0.18 inch per day for the same period according to Kruse and Haise (1974). The apparent differences in daily pan evaporation between Fairplay, Garo, and Antero Reservoir could not be verified during 1977-78 because of insufficient data from the Garo station. Part of this difference could be attributed to non-uniform operation of the evaporation pans. Hansen and others (1978) mapped a slight increase in annual evaporation from Antero Reservoir towards Fairplay but the amount of site-specific data available for this area was limited at the time the map was developed.

The relationship between seasonal (May-September) precipitation measured at Hartsel from 1940 through 1964, seasonal precipitation measured at the Antero Reservoir station from 1962 through 1976, and seasonal precipitation measured for this study at the Jefferson, Fairplay, and Antero Reservoir stations from 1977 through 1979 is shown in figure 4. The data for this study at Antero Reservoir are plotted separately from data reported by the U.S. Weather Bureau (1940-79) because the Weather Bureau data reported during 1977 through 1979 covers minor periods not analyzed by analyses of variance.

Mean seasonal precipitation at the Antero Reservoir station has been less than the normal seasonal precipitation (1931-60) at Hartsel. In addition, with the exception of precipitation during 1977 at the Antero Reservoir station, seasonal precipitation during 1977 and 1978 at all stations was less than the 17-year mean seasonal precipitation at Antero Reservoir. In 1979 all stations had greater seasonal precipitation than the 17-year mean seasonal precipitation at Antero Reservoir. Hansen and others (1978) show a mean April-September precipitation value of less than 10 inches for the Antero Reservoir area and 12 to 14 inches for the Jefferson-Fairplay area. The U.S. Weather Bureau (1964) map of normal May-September precipitation shows a value of less than 8 inches for Antero Reservoir, approximately 8 inches for Fairplay, and approximately 9 inches for Jefferson. Therefore, it appears that precipitation during 1977 and 1978 was less than the normal precipitation, and during 1979 might have been slightly above the precipitation normally occurring during the growing season in the area.

Air-temperature data also have been collected at the Antero Reservoir station since 1962 (fig. 5). The average (arithmetic mean of maximum and minimum temperatures) seasonal (May-September) air temperature at the Antero Reservoir station for 1962-79 was 51.2° Fahrenheit. During 1977, the seasonal air temperature was greater than this long-term average, while during 1978 it was about equal to it. Seasonal air temperature during 1979 was slightly below this long-term average. All data shown in figure 5 are from the U.S. Weather Bureau (1940-79).

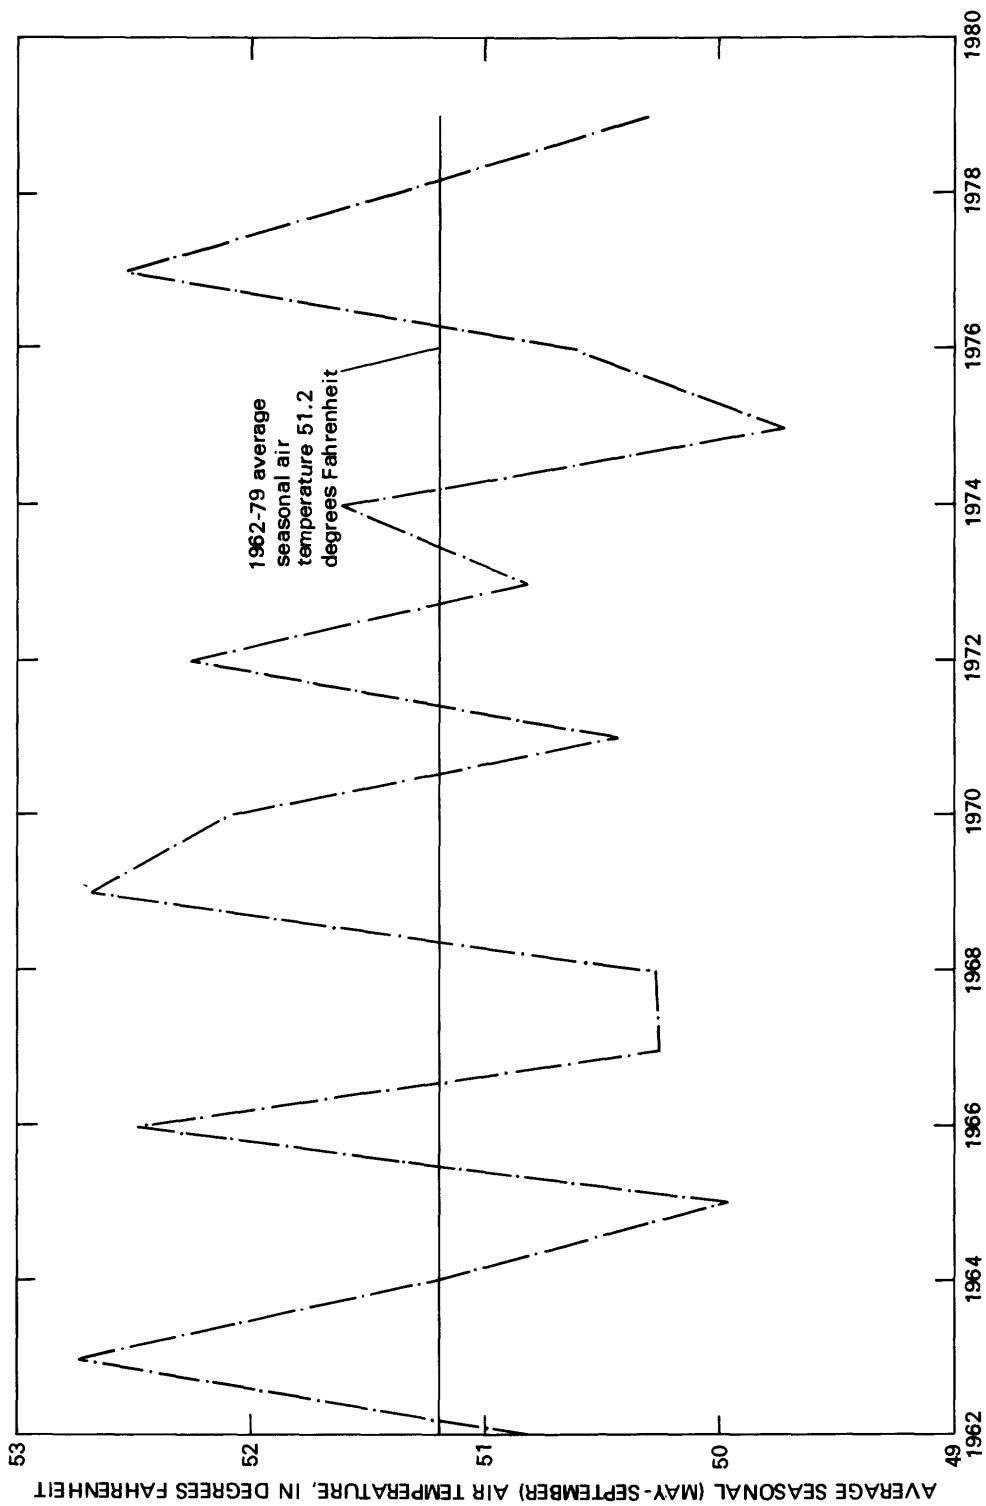

Figure 5.—Average May-September air temperature, Antero Reservoir station, 1962-79.

## SUMMARY AND CONCLUSIONS

Maximum and minimum air temperature, daily pan evaporation, daily precipitation, and daily solar radiation were measured at Jefferson, Fairplay, Garo, and Antero Reservoir stations during the growing seasons (May-September) of 1977, 1978, and 1979. Mean daily air temperature and daily relative humidity were only measured in 1977 and 1978 at these stations. Variations in the climatic characteristics between the Jefferson, Fairplay, and Antero Reservoir stations were analyzed using analysis of variance and a 1-percent least-significant-difference test; insufficient data was obtained at the Garo site for statistical analyses. The analysis can be summarized as follows:

1. Daily maximum air temperature did not differ between the Jefferson and Fairplay stations.
2. Daily pan evaporation was not different between the Fairplay and Antero Reservoir stations.
3. Precipitation did not differ between any of the stations.
4. All other climatic characteristics varied between the Jefferson, Fairplay, and Antero Reservoir stations.

When the study data was compared to historical precipitation data at Hartsel and Antero Reservoir, it was found that the 1977-78 growing seasons were drier than the long-term mean for the area, and that 1979 was wetter than the long-term mean for the area. Also, 1977 and 1978 were slightly warmer and 1979 slightly cooler than the 17-year average seasonal temperature at Antero Reservoir.

Estimated potential evapotranspiration was calculated using the Penman (1948) equation for the Jefferson, Fairplay, and Antero Reservoir stations. The estimates of potential evapotranspiration did not differ significantly between any of the stations. Data for the climatic characteristics--wind, solar radiation, relative humidity, and air temperature--are necessary for use of the Penman equation. Each of these characteristics varied significantly between the Jefferson, Fairplay, and Antero Reservoir stations. When incorporated into the Penman equation, the combined effect of the individual variations in the climatic characteristics was reduced, yielding statistically similar estimates of potential evapotranspiration. Therefore, no single climatic characteristic may be used to indicate spatial variations of potential evapotranspiration in the South Park area. The variations in solar radiation between the Jefferson, Fairplay, and Antero Reservoir stations indicate that solar radiation needs to be measured at any site dealing with evapotranspiration in the South Park area.

Table 5.--Climatic data, Fairplay station, May-September 1977, 1978 and 1979

TEMPERATURE MAX: Maximum daily air temperature  
TEMPERATURE MIN: Minimum daily air temperature  
PAN WATER MAX: Maximum daily water temperature of  
evaporation pan  
PAN WATER MIN: Minimum daily water temperature of  
evaporation pan  
PRECIP: Daily precipitation  
PAN EVAP: Daily pan evaporation  
DAILY AVG TEMP: Daily average air temperature  
DAILY AVG REL HUM: Daily average relative humidity  
SOLAR RAD: Daily average solar radiation  
F: Degrees Fahrenheit  
IN: Inches  
MI: Mile  
LY: Langley's per minute  
\*\*\*: Represents missing data
